No rhino, however, is doing worse than the northern white. Its native habitat, in Central Africa, was roiled by civil wars in the late 20th century, making conservation basically impossible. By the 1970s, a population of thousands was reduced to just 700. By the mid-1980s, only 15 northern whites remained in the wild. By 2006, that number was four — and they seem to have disappeared by 2008, almost certainly the victims of poachers. The northern white rhinoceros had been eliminated from its native range.

Fortunately, there was a backup plan: In the 1970s, a small reserve supply of northern whites had been captured and relocated to a zoo, as a kind of biological life-insurance policy. Unfortunately, these animals were dying off faster than they could reproduce. In 2009, the only remaining eligible breeders — Sudan and Suni and Najin and Fatu — were brought back to Africa, to a wildlife conservancy in Kenya. It was a moonshot: a hope that their native continent might stir something deep in the biology of the final four, that it might produce a miracle.
